ROVIRA CLAVÉ LAB — SPATIAL MULTI-OMICS OF CANCER CLONES

A mark for a group that studies how cell clones find their place in a tumor — and, in cooperation or competition, hold it.

THE MARK

The lattice is every cell type in a tissue, laid out as the grid of possible arrangements from Figure 1 of the group's brief. Out of that field, one small cluster resolves into a stable, connected pattern — two interleaved populations, drawn in the two-channel palette of multiplexed tissue imaging. It reads equally as a clone establishing territory in a tumor, or as a MIBI image resolving signal out of forty overlaid channels: the group's two central instruments, in one glyph.

COLOR

Palette

Ink and paper carry the identity; cyan and magenta are reserved for marking cell populations, echoing false-colour channels in multiplex imaging. Slate is the unresolved, unmarked field.

Ink

LOGO SYSTEM

Variations

FULL COLOR

REVERSED, ON INK

SINGLE COLOR / STAMP

Minimum clear space around the mark equals the radius of one cell (14px at the reference 240px size). Do not scale below 24px — below that, retire to the single-color stamp.

IN USE

Applications

DON'T

- Don't recolor the cluster outside cyan/magenta — the two-channel read is the point.
- Don't rotate or mirror the lattice; its grid must stay orthogonal.

- Don't add a drop shadow, gradient, or outline glow to the mark.
- Don't stretch the wordmark to fill a width — scale it, don't distort it.
- Don't pair the mark with unrelated science iconography (DNA helices, beakers, microscopes).
